1 System Components

1.1 Von Neumann Architecture

Components:

- **CPU**, Central Processing Unit
- **Memory**, Program and Data
- **In-/Output**-Unit, Peripherals
- **Bus-System**: Communication

One *shared bus and memory* for program and data.

1.2 Harvard-Architecture

basically same as Von Neumann, with the difference, that there are *two separate bus systems* for program and data

1.3 Numerical Systems

Numerical value Z_B of a n -digit, integer number with base B ($B \geq 2$):

$$Z_B = \sum_{i=0}^{n-1} x_i \cdot B^i$$

Decimal	Dual / Binary	Hexadecimal
197	0b1100'0101	0xC5
$B = 10$	$B = 2$	$B = 16$
$= 1 \cdot 10^2 +$ $9 \cdot 10^1 +$ $7 \cdot 10^0$	$= 1 \cdot 2^7 + 1 \cdot 2^6 +$ $0 \cdot 2^5 + 0 \cdot 2^4 +$ $0 \cdot 2^3 + 1 \cdot 2^2 +$ $0 \cdot 2^1 + 1 \cdot 2^0$	$= C \cdot 16^1 + 5 \cdot 16^0$ $= 12 \cdot 16^1 + 5 \cdot 16^0$

The amount of presentable numbers is B^n . The highest presentable number is $B^n - 1$. Calculated from $x_i = B - 1$ for $n - 1 \geq i \geq 0$

1.4 hex / binary

H	D	B	Dec	Bin
0	0	0000	16	2^5 (max 31)
1	1	0001	32	2^6 (max 63)
2	2	0010	64	2^7 (max 127)
3	3	0100	128	2^8 (max 255)
4	4	0101	256	2^9 (max 511)
5	5	0110	512	2^{10} (max 1'023)
6	6	0111	1'024	2^{11} (max 2'047)
7	7	1000	2'048	2^{12} (max 4'095)
9	9	1001	4'096	2^{13} (max 8'191)
A	10	1010	8'192	2^{14} (max 16'383)
B	11	1011	16'384	2^{15} (max 31'767)
C	12	1110	32'768	2^{16} (max 65'535)
D	13	1011		
E	14	1011		
F	15	1011		

1.5 Signed numbers

two's compliment is being used

$$Z_{signed} = -x_{n-1} \cdot 2^{n-1} + \sum_{i=0}^{n-2} x_i \cdot 2^i$$

most significant bit is negative

Example: -1 as 16-bit Hex = 0xFFFF

Conversion:

1. Invert binary : $-6 \rightarrow 0110 \rightarrow 1001$
2. increment by 1 : $1001 + 0001 \rightarrow 1010$

1.6 carry / overflow

Carry is set on crossover between lowest and highest number

Overflow happens on crossover between highest absolute values

1.7 Bit groups

Nibble/Tetrad has the size of 4 bits

Byte has the size of 8 bits

Word is MC9S08JM60 specific, it has 16 bits

1.8 Quantity of address lines

$$1\text{ K} = 2^{10} = 1024\text{ Bit} \hat{=} 10\text{ Adresslines}$$

$$64\text{ K} = 2^{16} = 65536\text{ Bit} \hat{=} 16\text{ Adresslines}$$

example, $32\text{K} \times 8$ memory storage space:

bits storage: $32 \cdot 2^{10} \cdot 8 = 2^5 \cdot 2^{10} \cdot 2^3 = 2^{18} \rightarrow 18\text{ Bits}$

number address lines: $32 \cdot 2^{10} = 2^{15} = 32\,768$

highest address: $2^{18} - 1 = 0x7FFF = 262\,143$

1.9 Microprocessor vs Microcontroller

Microcontroller contains CPU (Processor), Peripherals (I/O) and Memory (RAM / ROM). Basically a small computer.

Microprocessor has only CPU and some integrated Circuits.

1.10 CPU components

ALU (Arithmetic Unit), AKKU (Accumulator), PC (Program Counter), Busses, Instruction-Register, Address-Register, Operand-Register, Control Unit, ..

1.11 Instruction Cycle Steps

1. instruction fetch
2. instruction decode
3. (operand fetch)
4. instruction execute
5. next address and inc PC

1.12 Types of MCU Registers

AKKU, PC, Instruction-Register (decoder), Operand-Register

2 Compiling

2.1 Codewarrior Designflow

2.2 Programming Language

High level programming languages are:

- portable
- efficient (normally)
- Better readable
- easier to maintain

High level programming languages are usually preferred, if enough computational power and memory is available. Assembler is often used, if the application:

- is time critical and needs exact timing
- timing of the high level programming language to unpredictable is

2.3 Assembler Code-Format

	Label	Instruction	Operands	comment
Ex1	Limit:	EQU	\$CD	; define limit
Ex2	Start:	LDA	#Limit	; load limit

Instruction: is a command for the processor

Directive: are instructions that direct the assembler / compiler to do something

	Type	Directed to	Results in program code
Ex1	Instruction	Target CPU	Yes
Ex2	Directive	Assembler	Only indirect
	Comment	Programmer	No

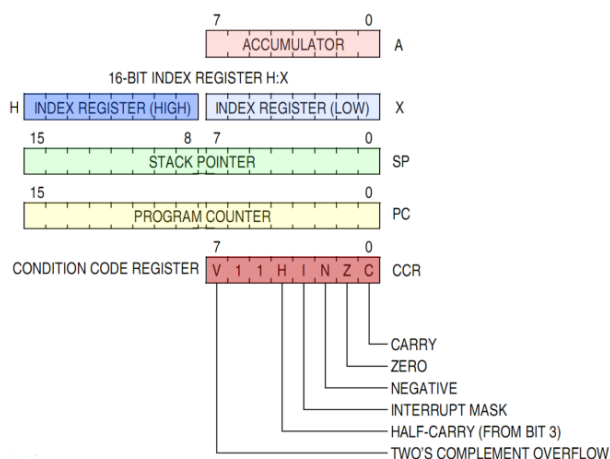

2.4 Parameter file

The Parameter file (*.prm) is used for by the Linker. It takes the machine code and defines the location on the controller. It is important, so that jumps work correctly. It contains:

- Memory-Map of the Prozessor (Location and size of Flash, RAM, ..)
- Extra definitions, where which parts of the code on the Controller should be located

3 Assembler & HCS08

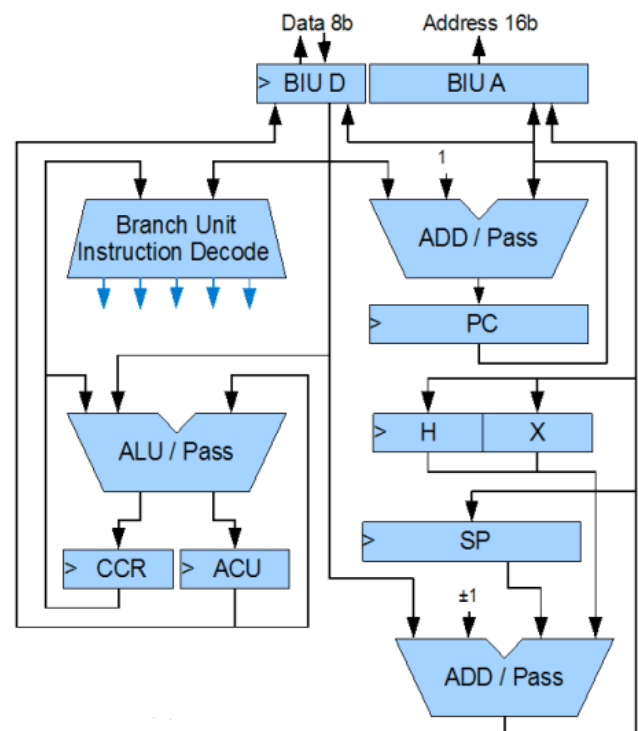

3.1 HCS08 CPU Registers

Registers the HCS08 contains:

- HX Register
- PC
- Akku
- Stack Pointer
- CCR

3.2 HCS08 Processor

- 8 Bit, Von Neumann architecture
- **BIU** Bus Interface Unit
- **PC** Program Counter
- **ACU** Accumulator
- **ALU** Arithmetic Logic Unit
- **CCR** Condition Code Register (Collection of status flags)
- **SP** Stack (LI-FO, Pointer for Context and Parameter)
- **H:X** Index Register

3.3 Memory Mapping

Access to the directpage (0x0000 - 0x0AF) needs less cycles, since the address is only 1 Bytes long.

3.4 Register configuration HCS08

```
// define the dataflow direction input = 0 /
    output = 1
PTADD = 0x04;

// set output value
PTAD = 0x04;
// read value
uint_8 val = PTAD;

// set pullup enable port
PTADD = 0x00;
PTAPE = 0x04;
```

Reg. Name Description

PTxDD	Data Direction of Port x
PTxD	Data value of Port x
PTxPE	Set Pullup Enable of Port x (PTxDD needs to be 0)

Pullup Enable is used to pullup the value of the output to 1. This is usually used on a bus system to prevent a short circuit.

3.5 Differences of Operations

Comparing different operations, following should be taken in consideration:

- number of cycles
- memory usage, 8bit (directpage) / 16bit
- Set CCR bits / flags
- Used registers

- Address modes

4 Assembler Directives & Addressing Modes

4.1 Directives

Directive	Description
SECTION	Defines the beginning of a relocatable section
EQU	Assigns an expression to a name. Not redefinable
DC	Defines one or more constants and their names. Will be stored at the set location
DS	Allocates memory(RAM) for variables

The Assembler-Directive **SECTION** defines program- and data section. Those section can be moved freely within the memory (relocative assembling), **after** the **assembly** process is finished.

The final memory area location happens after the linking process. The locations of those sections can therefore be defined in the **Linker-Parameterfile**.

4.2 Basic Assembler Program

```
; include definitions
include 'MC9S08JM60.inc'

; -- globals
GLOBAL _Startup ; define start of programm
GLOBAL main
GLOBAL dummy ; Dummy Interrupt Service Routine

; -- equations
StackSize: EQU $60 ; stack size
pi: EQU 31416 ; example of random equ

; -- stack
DATA_STACK: SECTION
TofStack: DS StackSize-1 ; definiton of "
Top of Stack"
BofStack: DS 1 ; definition of "
Bottom of Stack"

; -- create space for data
DATA: SECTION
var1: DS 1 ; Example of a 1 Byte
Variable
Array1: DS $20 ; Example of an Array of $20
Bytes

; -- setup constants
CONST: SECTION
Maskel: DC.B %00000001
Parameter1: DC.B $3A ; DC with a point
Parameter2: DC.W 57100 ; word with int
value
Reserve_Par: DS 16 ; reserve empty 16
Bytes
VarArray: DS.W 3 ; reserve 3 Words
STRING1: DC.B 10, "Hello", $0D

; -- program start (initialisation)
PROGRAMM: SECTION ; Code Segment
```

```

_Startup:                ; Resetvektor points to
    this
Stackinit: LDHX    #(BofStack+1)
    TXS                ; decrement TXS, thats
                    why +1 BofStack
    LDA    #$00
    STA    SOPT1    ; Disable Watchdog

; -- actual program
main:
    ; turn on backlighths of the car
    BSET    PTDD_PTDD2, PTDD
    BSET    PTDDD_PTDDD2, PTDDD

    CLR     RamLoc

    BCLR    PTGDD_PTGDD0, PTGDD
    BCLR    PTGDD_PTGDD1, PTGDD
    BCLR    PTGDD_PTGDD2, PTGDD
EndlessLoop:
    ; load joystick values
    MOV     RamLoc, PTGD
    JMP     EndlessLoop

; (=ensure program end if endlessloop is
missing)
EndLoop:    BRA     *

; catch any unexpected interrupts
dummy:      BGND
            BRA     dummy

```

4.3 Addressing Modes

- **Immediate:** 1 Byte operand in instruction (LDA #\$01)
- **Inherent:** no operand required (e.g. NOP, INCA..)
- **Direct:** onlu direct page, 1 address Byte
- **Extended:** whole 64k area, 2 address Bytes
- **Indexed:** with SP (Stack pointer) or HX (7 sub modes)
- **Relative:** for branches, $PC=PC+2+two's\ compl.$

Different addressing modes of the same instruction type use different operation codes (e.g. LDA-MM: A6; LDA-DIR: B6).

4.3.1 Immediate (IMM)

Immediat addressing mode: the following Byte of the operation code is immediately used as the operand.

Example: **LDA #\$1C**

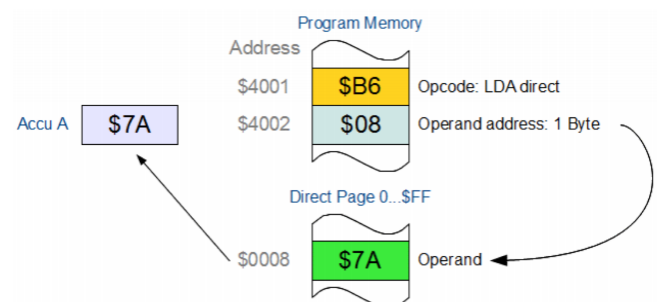

4.3.2 Inherent (INH)

Inherent addressing mode: no explicit operand address needed. All operands are in the CPU-registers

Example: **INCA**

4.3.3 Direct (DIR)

Direct addressing mode: After the operation code, the **1-Byte** operand address follows in the program memory. Only operands in the address section between \$00 and \$FF are supported. (The Direct Page Registers 0x00-0xAF, Direct Page RAM 0xB0-0xFF)

Example: **LDA \$08**

4.3.4 Extended (EXT)

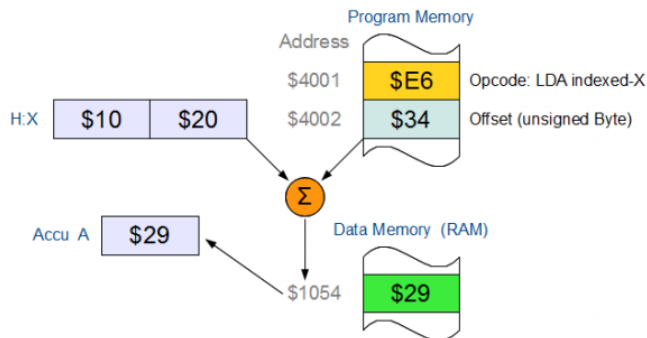

Extended addressing mode: After the operation code, the **2-Byte** operand address follows in the program memory.

Supports the whole address section between 0x0000 - 0xFFFF. But is also slower.

Example: **LDA \$34,X**

4.3.5 Indexed (IX1)

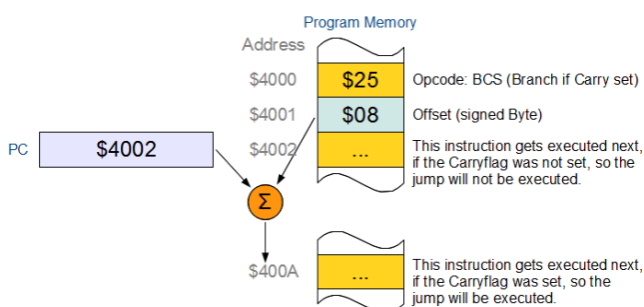

Indexed addressing mode: uses the **HX** or **SP** register. Through indexed addressing the final assigned operand address is dependent from the program behaviour (address arithmetics).

Following are sub modes of the indexed addressing mode

IX	Indexed addressing with H:X , without offset	LDA X
IX1	Indexed addressing with H:X and 8-bit offset	LDA \$34, X
IX2	Indexed addressing with H:X and 16-bit offset	LDA \$34A5, X
IX+	Indexed addressing with H:X and H:X Increment . Only for MOV and CBEQ (Compare Accu with value on the address that is stored in the H:X register. If values are equal, jump to Label and increment H:X) instructions	CBEQ X+, Label
IX1+	Same as IX+ , with Increment and 8-bit offset (Only available for instruction CBEQ)	CBEQ \$34,X+, Label
SP1	Same as IX1 , but with Stack-pointer SP instead of H:X .	LDA \$34, SP
SP2	Same as IX2 , but with Stack-pointer SP instead of H:X .	LDA \$34A5, SP

4.3.6 Relative (REL)

PC relative addressing mode: is only used with **BRANCH**-Instructions.

The following Byte after the operand is a **two's complement** offset to the already increased program counter.

The address range with relative addressing is -126 to +129. 129, since the PC is incremented before and after the jump (+2).

5 Assembler Addressing & Programming

5.1 Assembler Instructions

There are 3 main type of instructions:

- **Data Transport**
- **Operations** (Arithmetic, Logic, Bit-manipulation, Shift and Rotation)
- Program **Branches** with jump and branch operations

5.2 Transport Operations

	Operation	Example
L	Load	LDA, LDH, LDHX; PULA, PULX (Stackoperations)
S	Store	STA, STX, STHX; PSHA, PSHZ (Stackoperations)
T	Transfer	TAP, (CCR = Accu.), TPA, TAX, TSX
M	Move	MOV

5.3 Arithmetic Operations

ADD	Adds given operand to the ACC.
SUB	Works equivalent to the addition.
ADC & SBC	Include Carry bit and support additions and subtractions with numbers with more than 8 bits.
MUL	Multiplies the content of the accumulator A with the content of the index register X and stores the 16-bit result in X:A (MSB in X, LSB in A) only unsigned.
DIV	divides the 16-bit dividend in H:A (MSB in H, LSB in A) with the divisor in the index register X. The 8-bit result is written to A. If an overflow or division by 0 occurs, the Carry-bit is set. only unsigned.

Results of arithmetic instructions are saved on the HCS08 either in the X-Register or AKKU

5.4 Flags

CC	Name	Condition	Relevant for	
Z	Zero	Result = 0	unsigned	signed
N	Negative	Result < 0		signed
C	Carry	0 > Result > 255	unsigned	
V	Overflow	-128 > Result > 127		signed

Half-Carry is used for binary-coded decimal calculations

ADD instruction

C: A7&M7 | M7&R7 | A7&R7
 V: A7&M7&R7 | A7&M7&R7
 N: R7
 Z: R7&R6&R5&R4&R3&R2&R1&R0

SUB instruction

C: A7&M7 | M7&R7 | A7&R7
 V: A7&M7&R7 | A7&M7&R7
 N: R7
 Z: R7&R6&R5&R4&R3&R2&R1&R0

A (Operand 1)

M (Operand 2)

R (Result 1)

5.5 Logical Operations & Bit Masking

```
B7: EQU $80 ; Mask for Bit 7
B6: EQU $40 ; Mask for Bit 6
:
:
B0: EQU $01 ; Mask for Bit 0

ORA # (B6 | B3) ; Set Bit 6 and 3 in ACCU
AND # (B5 | B4) ; Delete all Bits in ACCU except
                  Bit 5 and 4
```

AND logical AND-operation
ORA logical OR-operation
EOR logical XOR-operation
BCLR n,Addr Delete Bit n on a specific memory address
BSET n,Addr Set Bit n on a specific memory address
BIT Addr Bitwise AND operation of Accu with content of Addr, without changing content of Accu and Addr. Affects only **N-** and **Z-Flags**.
CLC Delete Carry-Flag C
SEC Set Carry-Flag C
CLI Delete Interrupt-Mask Bit I (Interrupt enable)
SEI Set Interrupt-Mask Bit I (Interrupt disable)

5.6 Shift- and Rotation Operations

in direction MSB (left)

in direction LSB (right)

Logical Operations:

Arithmetic Operations:

Multiplication by 2, ASL=LSL

Division by 2

5.7 Relative Branching

Unconditional Branch

Oper.	Meaning
BRA	Branch always
BRN	Branch never
BSR	Branch to subroutine

Testing a Single Flag

Oper.	Test	Meaning
BEQ	Z=1	Branch if equal
BNE	Z=0	Branch if not equal
BCS	C=1	Branch if Carry set
BCC	C=0	Branch if Carry clear
BMI	N=1	Branch if Minus
BPL	N=0	Branch if Plus

Arithmetic Comparison of Accu and Memory Location

Oper.	Test	Format
BGT	>	signed
BHI		unsigned
BGE	≥	signed
BHS, BCC		unsigned
BLE	≤	signed
BLS		unsigned
BLT	<	signed
BLO, BCS		unsigned
BEQ	=	signed
		unsigned

5.8 Branching Compare-Operation

Compare instructions are **subtraction operations** that change status flags, but leave the data registers unchanged.

CMP opr8 Compare content of **ACCU** with 8-bit operand

CPX opr8 Compare content of **X-Register** with 8-bit operand

CMP opr8 Compare content of **HX-Register** with 16-bit operand

Example, Test if a value is bigger or smaller than another value, branch afterwards

```
LDA Op1
CMP Op2 ; Calculates (Op1-Op2) and sets flags
BMI Label ; Branch if Op2 > Op1 (N=1) to Label
```

5.9 Direct relative Branching

Those Branches are dependent on a single Bit of a memory located in the **Direct Page**.

```

BRCLR n,Addr,Label ; Branches to Label, if Bit
                    ; address Addr is not set (
                    ;   n of value on      Addr only DIR)
BRSET n,Addr,Label ; Branches to Label, if Bit
                    ; address Addr is set (Addr
                    ;   n of value on      only DIR)

```

6 Subroutines & Stack

6.1 Stack

Stack grows from high addresses to lower

```

Stacksize: EQU $40
:
DATA:      SECTION
TofStack:  DS Stacksize-1 ; reserve stack
BofStack:  DS 1
:
PROGRAM:   SECTION
LDHX # (BofStack+1) ; H:X := Bottom
              of Stack
TXS              ; SP := HX -1
:
; save CPU-Status on stack
PSHA ; Akku auf Stack
PSHX ; X-Register auf Stack
:
; restore CPU-Status from stack
; order is important (LIFO!)
PULX ; X-Register
PULA ; Akku

```

Stacks are used for:

- Subroutine calls (save return address)
- Store context
- Store parameters
- Store local variables

malloc (heap) and global variables are not stored on the stack.

6.2 Subroutines

BSR/JSR push and inc. PC
 RTS pull and inc. PC
 Parameters passing on stack (used by C)

Local Variables saved on stack (used by C)

subroutines enable following:

- **less memory usage**; repeated command sequences are stored only once
- **less development effort**; tested command sequences can be reused
- **less error prone**; enable modular way of building software
- **higher team productivity**; multiple people can work parallel on different code sections
- **shorter compile time & libraries**; different parts of the code can be compiled separately

The only **negative** about subroutines is calling of subroutines is **slower**. Time is needed for passing parameters and saving the context on the stack

6.3 Stack size

To analyze the used stack size, it is helpful to create a tree with the subroutines, their calls and used stack space.

It is also possible to figure out the stack usage by filling the program-stack at the start with a bit pattern like 0xdeadbeef and stress test the program as much as possible. At the end, this will show which part and how much of the stack has been used during the program execution.

7 Timer and Interrupts

7.1 Modulo Counter

7.2 Modulo Frequency

$$T_{TOF} = (MOD + 1) \cdot PS / f_{CLK}$$

- T_{TOF} : Time between two Timer-Overflow events
- MOD: Value of the Modulo set
- PS: Prescaler value
- f_{CLK} : frequency of the controller

To calculate the modulo, the frequency (Clock Source) needs to be selected and the prescaler needs to be defined. To calculate the Modulo value, following can be used. The Modulo is 2 Bytes, so it needs to be between $0 < MOD < 65536$

$$MOD = \left(\frac{T_{TOF} \cdot f_{CLK}}{PS} \right) - 1$$

7.3 Timer Control Registers

Address	Reg-Name	Bit-Name							
0x0060	TPM2SC	TOF	TOIE	CPWMS	CLKSB	CLKSA	PS2	PS1	PS0
0x0061	TPM2CNTH	Bit 15	14	13	12	11	10	9	Bit 8
0x0062	TPM2CNTL	Bit 7	6	5	4	3	2	1	Bit 0
0x0063	TPM2MODH	Bit 15	14	13	12	11	10	9	Bit 8
0x0064	TPM2MODL	Bit 7	6	5	4	3	2	1	Bit 0
0x0065	TPM2C0SC	CH0F	CH0IE	MS0B	MS0A	ELS0B	ELS0A	0	0
0x0066	TPM2C0VH	Bit 15	14	13	12	11	10	9	Bit 8
0x0067	TPM2C0VL	Bit 7	6	5	4	3	2	1	Bit 0
0x0068	TPM2C1SC	CH0F	CH0IE	MS0B	MS0A	ELS0B	ELS0A	0	0
0x0069	TPM2C1VH	Bit 15	14	13	12	11	10	9	Bit 8
0x006A	TPM2C1CL	Bit 7	6	5	4	3	2	1	Bit 0

SC = Status&Control, CNT = Counter, MOD = Modulo, V = Value; H = High-Byte, L = Low-Byte

CLKSB:CLKSA	TPM Clock Source to Prescaler Input
00	No clock selected (TPM counter disable)
01	Bus rate clock
10	Fixed system clock
11	External source

Table 16-4. Prescale Factor Selection

PS2:PS1:PS0	TPM Clock Source Divided-by
000	1
001	2
010	4
011	8
100	16
101	32
110	64
111	128

7.4 Polling and Interrupts

A MC-System has to react instantly to events (internal or external) (e.g. measure value monitoring, serial communication).

The **instant of time** of these events is **not known in advance**.

There are two ways to react to those kind of events:

- **Interrupt** = Exception handling
enables **realtime capable (+)** systems (depends on interrupt **latency**). **Fast reaction time** through automatic reaction to events and interrupt of the program to execute an Interrupt-Service-Routine (ISR). Needs substantial effort for **state backup (-)**, because the instant of the program interruption is unknown.
- **Polling** = cyclic requesting
Shorter program interruption (+). Since the instant of time is known during programming, the state can be backed up more efficiently.
easier to understand / debug (+)
Waste of calculation time (-) if events occur rarely

Each MCU holds an Interrupt-Logic to realise real-time systems.

7.5 Interrupt execution

1. Interrupt called
2. Save current state onto stack
3. Call function
4. By Programming - clear interrupt flag
5. go back to code
6. load saved state from stack
7. keep running where stop before interrupt

7.6 Save Interrupt State

On entrance to an ISR the CPU-State is backed up automatically to the Stack.

Note: The **H-Register** must be saved „manually“ on the HCS08 (only with Assembler)

7.7 Difference ISR and Subroutines

ISR = Interrupt Service Routine / Interrupt Subroutine

	ISR	Unterprogramm
Call	spontaneous	BSR/JSR
State backup	automatic	Program (manual)
Return jump	RTI	RTS

7.8 Interrupt Sources Priority

In the MC9S08JM60 there are 29 Interrupt Sources, that are sorted by priority in the Interruptvector-Table

1x	Real-Time Clock				
1x	IIC Module				
1x	Comparator Module				
1x	A/D-Converter				
1x	Keyboard-Interface				
6x	SCI 1/2 Module				
10x	Timersystem				
1x	USB Module				
2x	SPI 1/2 Module				
1x	Clock Generator				
1x	Low-Voltage Detection				
1x	External IRQ Pin				
1x	SW-Interrupt (SWI)				
1x	Reset Interrupt				

maskable

not maskable
partwise maskable

lowest priority

highest priority

```

VECTOR ADDRESS 0xFFE0 errISR_TPM20 // TPM1
overflow
VECTOR ADDRESS 0xFFE2 errISR_TPM1CH5 // TPM1
channel 5
VECTOR ADDRESS 0xFFE4 errISR_TPM1CH4 // TPM1
channel 4
VECTOR ADDRESS 0xFFE6 errISR_TPM1CH3 // TPM1
channel 3
VECTOR ADDRESS 0xFFE8 errISR_TPM1CH2 // TPM1
channel 2
VECTOR ADDRESS 0xFFEA errISR_TPM1CH1 // TPM1
channel 1
VECTOR ADDRESS 0xFFEC ifrFrontISR // TPM1
channel 0

```

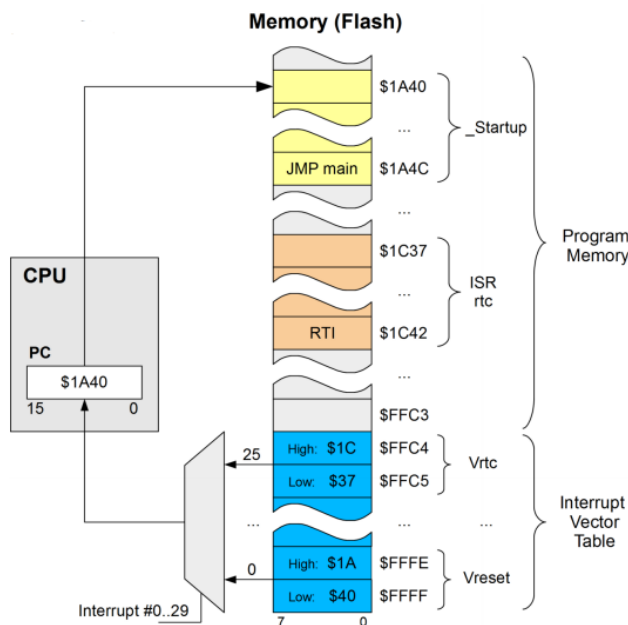

By default the HCS08 does **not** support **nested Interrupts**, because the I-Flag gets set on an entrance into an ISR.

If there are more Interrupt demands, the ISR with the highest priority (lowest vector number) is called first

7.9 Interrupt Counter

Setting the Interrupt Counter will set it always to 0.
Reading one of the Counter 8 Bit, the other one will be saved to a shadow register until read from.

7.10 Interrupt Vectortable

```

// Extract out of .prm File
VECTOR ADDRESS 0xFFC4 ISR_RTI // RTC
VECTOR ADDRESS 0xFFC6 errISR_IIC // IIC
VECTOR ADDRESS 0xFFC8 errISR_ACOMP // ACOMP
VECTOR ADDRESS 0xFFCA errISR_ADC // ADC
Conversion
...
VECTOR ADDRESS 0xFFDA motorBoosterISR // TPM2
overflow
VECTOR ADDRESS 0xFFDC errISR_TPM2CH1 // TPM2
channel 1
VECTOR ADDRESS 0xFFDE errISR_TPM2CH0 // TPM2
channel 0

```

7.11 Interrupt-Release Logic

7.12 Programming of Interrupts

Following is important for programming interrupts:

- Define **Interruptvectors**; at the place of the Interruptvector has to be the start address of the ISR (in CW definition in .prm file)
- Define and initialise **Stack**
- **Delete the Interrupt-Flags before** you release them, so that the Interrupt does not get fired right away.
- **Programming of ISR**; CPU-State gets backed up automatically (H-Register only through C-Compiler)
- **Delete the Interrupt-Flag in the ISR**
- **End the ISR with RTI** (is done automatically on usage of C-Compiler)
- Release Interrupts globally (**CLI**) in the main program (typically after initialisation part)

```

interrupt void myTofISR(void)
{
    // myTofISR function needs to be mapped
    // in the vectortable -> parameterfile (.
    prm).
    //reset the interrupt flag
    TPM1SC_TOF = 0;

    //run logic
}

```

```

void initTimer(void)
{
    //set module to 25780 / 0x64B4
    TPM1MODH = 0x64;
    TPM1MODL = 0xB4;
    //TPM1MOD = 25780;
    //Clock set to 1 MHz
    TPM1SC_CLKSA = 0;
    TPM1SC_CLKSB = 1;

    //define Prescaler to 128
    TPM1SC_PS0 = 1;
    TPM1SC_PS1 = 1;
    TPM1SC_PS2 = 1;

    // reset counter
    TPM1CNT = 0;

    // enable timer Overflow Interrupt
    // this should be the last action
    TPM1SC_TOIE = 1;
    // Reset the Timer Overflow Interrupt
    TPM1SC_TOF = 0;
}

void main(void)
{
    initTimer();
    //enable interrupts
    EnableInterrupts;
}

```

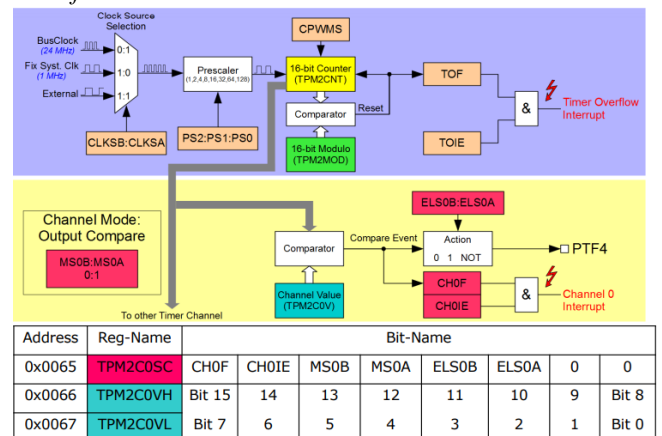

8 Output Compare & Input Capture

CPWMS	MSnB:MSnA	ELSnB:ELSnA	Mode	Configuration
X	XX	00		Pin not used for TPM - revert to general purpose I/O or other peripheral control
0	00	01	Input capture	Capture on rising edge only
		10		Capture on falling edge only
		11		Capture on rising or falling edge
	01	01	Output compare	Toggle output on compare
		10		Clear output on compare
		11		Set output on compare
	1X	10	Edge-aligned PWM	High-true pulses (clear output on compare)
		X1		Low-true pulses (set output on compare)
1	XX	10	Center-aligned PWM	High-true pulses (clear output on compare-up)
		X1		Low-true pulses (set output on compare-up)

8.1 Timer with Output-Compare

interrupt is occurring, when the content of the V-Register and of the counters have the same value.

```

void initTimer(void) {
    TPM1CISC_CH1IE = 1; //Channel 1 Timer 1
    //Interrupt enable
    TPM1CISC_MS1A = 1; //A=1 ; B=0 - Output
    //Compare
    TPM1CISC_MS1B = 0;
    TPM1CISC_ELS1A = 1; //A=1 ; B=0 - Toggle
    //Output on Compare
    TPM1CISC_ELS1B = 0;
    TPM1C1V = 0x95FF; //set 16bit channel value
    // (is compared with main timer, calc the
    // timer on the base of the clock)
}

interrupt void ISR_outCompare(void) {
    TPM1CISC_CH1F = 0 ; //Timer 1 Channel 1
    //overflowflag reset
    TPM1C1V += 0x95FF ; //Channel Value is set
    // to new value
    // (add with the value, on how much time
    // needs to pass)
}

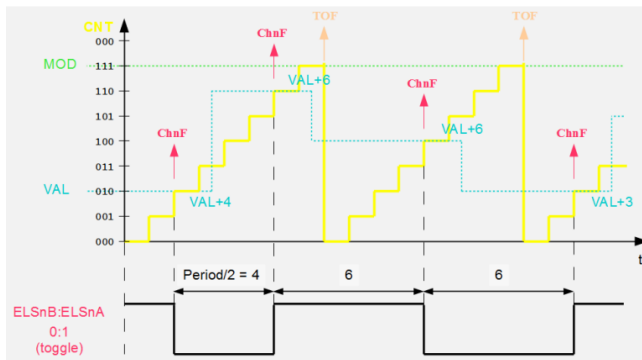

```

8.2 Usage Output Compare Mode

Output Compare is usually used to set / clear or toggle output pins.

The output compare mode can additionally be used to setup different timers on base of the same timer without

changing the $TPMxMOD$ value. To use the $TPMxCx$ output pin for other purposes, following needs to be set $ELSnA:ELSnB=00$

The value to increment can be calculated as following:

$$ChannelValue = \frac{T_{CHnF} \cdot F}{Prescaler} \quad \begin{array}{l} T_{CHnF}: \text{Target channel frequency} \\ F: \text{Clock frequency} \end{array}$$

8.3 Input Capture

Input capture is used on the timer pins. it enables reacting on input (rising/falling or both).

If an input capture happens, the interrupt is executed and the current counter is saved in the channels value register for further usage.

8.4 Logic Analyzer

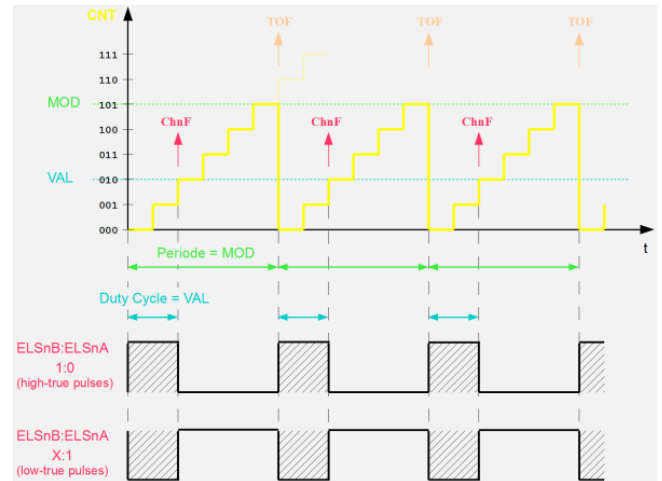

The old logic analyzer has modes for external clocks, but it is limited to memory

New Logic Analyzer will always use the internal clock and since it uses the computer, the memory is fine and oversampling is fine.

9 Pulse-Width Modulation (PWM)

9.1 Edge Aligned PWM

$VAL = 0$: Duty Cycle = 0%

$VAL > MOD$: Duty Cycle = 100%

- **High-true pulses:** Das bedeutet, dass true = 1 ist. Also solange der Channel Value > Counter ist, ist der ausgehende Pin = 1.
- **Low-true pulses:** Das bedeutet, dass true = 0 ist. Also solange der Channel Value > Counter ist, ist der ausgehende Pin = 0;

9.2 H-Bridge (Fast / Slow Decay)

Energy in the Magnetic field

Fast Decay: "Brake" after T1 & T4 on, deletion with D2 & D3 (2 x 0.7V Voltage drop → Power loss → eventually puls with T2 & T3)

Slow Decay: "Idle Running" after T1 & T4 on, delete with T2 & T4

9.3 PWM Code

```
void initTimer(void) {
    //set clock to 24 MHz
    TPM1SC_CLKSA = 1;
    TPM1SC_CLKSB = 0;
    //Prescaler to 0
    TPM1SC_PS0 = 0;
    TPM1SC_PS1 = 0;
    TPM1SC_PS2 = 0;
    // set Modulo to 2^16 -1 stellen.
    // (-1, to enable PWM to reach 100%)
    TPM1MOD = 65534;
}
```

```

}

void initPWM(void) {
    //Channel 2 to Mode Edge-Aligned PWM
    TPM1C2SC_MS2A = 1;
    TPM1C2SC_MS2B = 1;
    //set Channel 2 to "Low-true pulses", since
    LED rect to 0 as on
    TPM1C2SC_ELS2A = 1;
    TPM1C2SC_ELS2B = 1;
    //Channel 2 Channel Value = Modulo * 0.3,
    since set LED to 30%.
    TPM1C2V = 21844;
}

void main(void)
{
    // enable as output
    PTFDD_PTFDD0 = 1;

    initTimer();
    initPWM();

    for(;;);
}

```

10 IIC-Bus

10.1 IIC-Bus Properties

- 2 bidirectional wires (Clock: **SCL**, Data: **SDA**)
- Clock rates: **Standard 100 kHz**; **Fast 400 kHz**; **Fast Plus 1 MHz**; **High Speed 3,4 MHz**
- Master/Slave-architecture, multiple masters are possible (**Bus Arbiter**)
- Number of participants is limited by number of addresses and wire capacity
- Bus participants of different speeds are possible (**Clock Stretching**). Clock Stretching enables the slave to slow down the master.

10.2 IIC-Bus stages

- All bus participants use **Open-Drain Output stages** (no active **H-Level** possible).
- **External Pullup-Resistors** generate the **H-Level** (Default-State).
- All bus participants observe at all times the actual state of SCL (Clock) and SDA (Data).

IIC without hardware support:

If the IIC is not supported by the hardware, the open drain can be simulated. This is possible by setting the pins Internal pullup to 1 ($PTxPEN = 1$). Set the Output to 0 ($PTxDn = 0$). To write 1 ($PTxDDn = 0$) and 0 ($PTxDDn = 1$) use the datadirection. This will prevent any short circuits.

10.3 Bit-Transfer

SDA (Data) can be changed if SCL=0, and is evaluated when SCL=1.

10.4 Start-/Stop-Condition

*Start-/Stop-Conditions are always generated by the Master. As **protocol mismatch** they are detected by other Masters and Slaves and can easily be differentiated from normal data bits.*

*After a Start-Condition, the bus is **busy**.*

*After a Stop-Condition, the bus is **idle**.*

10.5 Byte Transfer (Blocks)

- Data transmission from transmitter to receiver is **Byte-wise (MSB-first)**.
- At the end of each byte, the **Receiver** generates an **Acknowledge-Bit**: **SDA = 0 = Ack** **SDA = 1 = No-Ack** Through the generation of No-Ack, a transfer can be cancelled (premature).
- A **Repeated-Start** (Sr) Condition can be generated by the active Master instead of a Stop-Condition, if the Master wants to continually use the bus
- A Slave can force a Master to slow transmission through **Clock Stretching**.

10.6 Slave Addressing

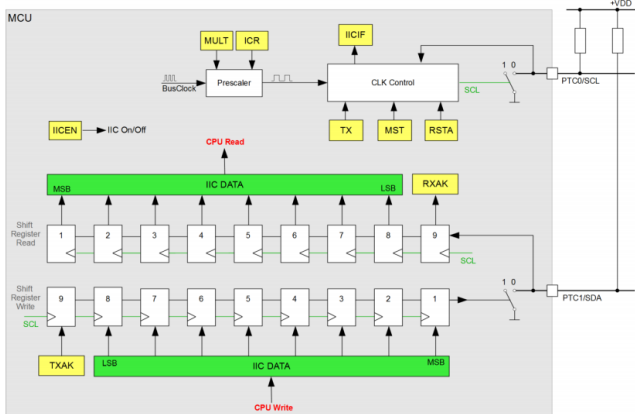

- In the first byte after the Start-Condition the master sends a **7-Bit Address**.
- A slave with this address has to answer in the 9th bit with an Ack-Signal.
- In the **8th bit** the master sends the **R/W** direction-bit:

R/W = 0 : Write : Master-Transmitter to Slave-Receiver

R/W = 1 : Read : Master-Receiver from Slave-Transmitter

- Combined R/W Transfer-formats are possible through Repeated-Start Condition.

10.7 Function Schema & Control Register

IICEN: Block enable

MST: master & busy

TXAK: ack enable

TCF: transfer done

BUSY: bus busy

SRW: slave R/W

RXAK: acknowledged

IICIE: Interrupt en.

Tx: transmit

RSTA: repeat start

$f_{IIC} = f_{BUS} / MULT \times f(ICR)$

IAAS: addressed

ARBL: arbitration lost

IICIF: int. Flag

0x0058	IICA	AD7	AD6	AD5	AD4	AD3	AD2	AD1	0	slave address
0x0059	IICF	MULT								freq. divider
0x005A	IICC	IICEN	IICIE	MST	TX	TXAK	RSTA	0	0	control register
0x005B	IICS	TCF	IAAS	BUSY	ARBL	0	SRW	IICIF	RXAK	status register
0x005C	IICD									data reg. (r/w)

- IICD**: 7 Bit Daten, 1 Bit R/W
- IICS_IICIF**: IIC Interrupt Flag wird gesetzt wenn: 1Byte transferiert wurde, Slave Adresse und angesprochene Adresse identisch sind oder Arbitration lost.
- IICS_RXAK**: 0=Acknowledge recieved, 1=no Acknowledge recieved.
- IICC_MST**: wechsel von 0 nach 1 generiert Stop.
- IICS_IICIF**: =1 resetet den Interrupt.
- IICC_TSAK**: =0 ein ACK wird nach empfangen eines Bytes gesendet, =1 kein ACK wird gesendet.

10.8 Baud rate

The IIC baud rate can be calculated as following (standard: 100 kbit/s = 100'000)

$$\text{baudrate} = \frac{f_{bus}[Hz]}{\text{mul} \cdot \text{Divider}}$$

10.9 Code I2C Module

```
void main(void)
{
    uint8 i;
    TPM1SC = 0x10; // Timer init -> 1MHz
    ifrRxFrontInit(); // Infrared init
```

```
motorInit(); // Motor init
i2cInit(); // init i2c
EnableInterrupts; // Interrupts enable
}

// Initialisiert den I2C-Bus
// -> enable I2C with 400 kHz SCL clock
frequency
void i2cInit()
{
    // Frequency Divider Register: zur
    // Einstellung der Baudrate
    IICF_ICR = 0x05; // 24 MHz/(2 * 30) = 400
    kHz
    IICF_MULT = 0x01; // IIC Baudrate =
    BusSpeed (Hz)/((MULT * SCLdivider)
    // SCLdivider -> Tabelle S.167
    // IIC Control Register
    IICC_IICEN = 1; // I2C enable
}

//Start
tError i2cStart(uint8 adr, bool write)

        while (!IICS_IICIF);

        // create stop Condition
        IICC_MST = 0;
        buf[length-1] = IICD;
    }
    else
    {
        IICC_TXAK = 1; // send no Ack that a
            Stop-Condition can be sent
        buf[0] = IICD; // Dummy-Read and
            therefor last transmission starten
        ...
        while (!IICS_IICIF); // wait till
            transmission finished
        IICS_IICIF = 1; // clear Interrupt-Flag
        IICC_MST = 0; // generate Stop-
            Condition
        buf[0] = IICD; // read last databyte
    }
}

```

11 RS-232

11.1 Protocol

9600 8-O-1 9600 Baud, 8 Data Bits, Odd Parity,
1 Stop Bit

Data Bits 0100 0111 = 0x47 = 'G'

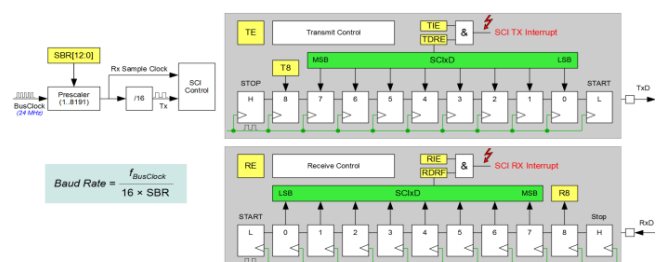

- RS-232 works with an **asynchronous** point to point transmission with separate **Rx** and **Tx** data wires (Receive/Transmit).
- Today more modern standards are used for the physical transmission of RS-232, e.g. USB or Bluetooth.
- In practice **most often the parity-bit is not used**, but instead a check is done on a higher protocol layer, e.g. **CRC-check sum**.

11.2 Transmission-protocols comparison

Following protocols are used often with MCUs for wire-bound transmission. (SPI «Serial Peripheral Interface» from Motorola, similar to Micro-wire of NI)

	RS-232	IIC	SPI	1-Wire
Duplex	full	half	full	half
Topology	point-to point	multi-master	master-slave	master-slave
Timing	asynchron	synchron	synchron	asynchron
Pin Count (w/out GND)	2	2	3 + #slaves (as ring: 4)	1
Typ. Data Rates [kbps]	10-100	100-3'400	1'000-15'000	16
Typical Application	off-board	on-board, address locations	on-board, streaming data	ultra low-cost/-power
Typical Devices	PC terminals	Sensors	ADC/DAC	Sensors
(other than MCU/DSP)		EEPROMS	Flash	

11.3 Function Schema & Control Register

0x0038	SCI1BDH	LBKDIE	RXEDGIE	0	SBR12	SBR11	SBR10	SBR9	SBR8	baud div H
0x0039	SCI1BDL	SBR7	SBR6	SBR5	SBR4	SBR3	SBR2	SBR1	SBR0	baud div L
0x003A	SCI1C1	LOOPS	SCISWAI	RSRC	M	WAKE	ILT	PE	PT	control reg 1
0x003B	SCI1C2	TIE	TCIE	RIE	ILIE	TE	RE	RWU	SBK	control reg 2
0x003C	SCI1S1	TDRE	TC	RDRF	IDLE	OR	NF	FE	PF	status reg 1
0x003D	SCI1S2	LBKDF	RXEDGIF	0	RXINV	RWUID	BRK13	LBKDE	RAF	status reg 3
0x003E	SCI1C3	RS	TS	TXDIR	TXINV	ORIE	NEIE	FEIE	PEIE	control reg 3
0x003F	SCI1D	Data								data r/w

11.4 Serial Bit-Synchronization

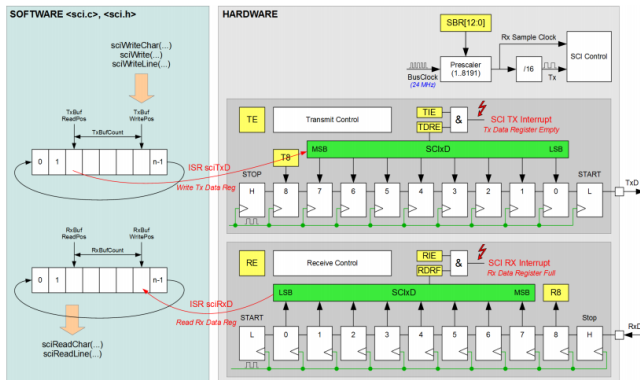

- Bit-Enable is the recovered bit clock roughly in the middle of each bit.
- Serial transmitting fast fiber optical systems (eg. SDH) need a similar bit clock recovery (mostly done with Phase Locked Loops - PLL).
- Missing parts: Byte-Enable should stop Counter0-15 - Reset should start it; bit sample eg. at positions 5, 7, and 9 – majority decision, 8-bit parallel load byte register; Tx.
- noise bit is set if the 3 bits (5, 7 and 9) are not the same.

11.5 Parity Bit

E: Even parity = even count num 1 => 0 uneven num 1 => 1

O: odd is other way around

11.6 Code RS232 with Ringbuffer

```
// sendqueue
static char tx1Buf[SCI1_TX_BUF_SIZE];
static uint8 tx1BufCount;
static uint8 tx1BufWritePos;
static uint8 tx1BufReadPos;

// receivequeue
static char rx1Buf[SCI1_RX_BUF_SIZE];
static uint8 rx1BufCount;
static uint8 rx1BufWritePos;
static uint8 rx1BufReadPos;

#define BUSCLOCK 24000000 // Hz
```

```
// init define baudrate; like 4800, 9600, 38400
void scilInit(uint32 baudrate)
{
    // Berechnung Baudrate normalerweise:
    SCIxBD = Busclock / (16 * Baudrate)
    SCIxBD = (uint16) (((BUSCLOCK * (uint32)
    10) / ((uint32) 16 * baudrate) + 5) /
    10);

    SCI1C3 = 0x0F; // activate
    error-Interrupts

    tx1BufCount = 0; // TX-Buffer
    tx1BufWritePos = 0;
    tx1BufReadPos = 0;

    SCI1C2_TE = 1; // turn sender
    on

    rx1BufCount = 0; // RX-Buffer
    rx1BufWritePos = 0;
    rx1BufReadPos = 0;

    SCI1C2_RE = 1; // activate
    receiver;
    SCI1C2_RIE = 1; // activate
    receiver interrupt
}

// error interrupt routine
interrupt void scilError(void)
{
    (void)SCI1S1;
    (void)SCI1D;
}

// receive data
interrupt void sclRxD(void)
{
    char ch;
    (void)SCI1S1; // read state to reset
    ch = SCI1D;
    if(rx1BufCount < SCI1_RX_BUF_SIZE)
    {
        rx1Buf[rx1BufWritePos] = ch;
        rx1BufCount++;
        rx1BufWritePos++;
        if(rx1BufWritePos == SCI1_RX_BUF_SIZE)
            rx1BufWritePos = 0;
    }
}

// write next byte from ringbuffer
interrupt void scilTxD()
{
    (void)SCI1S1;

    if(tx1BufCount != 0) {
        SCI1D = tx1Buf[tx1BufReadPos];
        tx1BufCount--;
        tx1BufReadPos++;
        if(tx1BufReadPos == SCI1_TX_BUF_SIZE)
            tx1BufReadPos = 0;
    } else {
        SCI1C2_TIE = 0;
    }
}

// write to the ringbuffer
char scilReadChar(void)
```

```
{
    char ch;
    while (rx1BufCount == 0);

    ch = rx1Buf[rx1BufReadPos];
    rx1BufCount--;
    rx1BufReadPos++;
    if (rx1BufReadPos == SCI1_RX_BUF_SIZE)
        rx1BufReadPos = 0;
    return ch;
}

// write a character
void scilWriteChar(char ch)
{
    while (tx1BufCount >= SCI1_TX_BUF_SIZE);

    tx1Buf[tx1BufWritePos] = ch;
    tx1BufCount++;
    tx1BufWritePos++;
    if (tx1BufWritePos == SCI1_TX_BUF_SIZE)
        tx1BufWritePos = 0;

    SCI1C2_TIE = 1;
}
```

12 Analog/Digital Converter

12.1 AD-Converter System

- Many sensor measure values are provided as an analog signal (e.g. temperature, pressure, velocity, etc.). For further processing, the values are converted into **R bits (resolution)** wide digital signals.
- Many MCUs are equipped with an integrated **A/D-Converter**, that can convert multiple analog input voltages from the MCU-Pins with **timemultiplexing**.

12.2 Successive Approximation

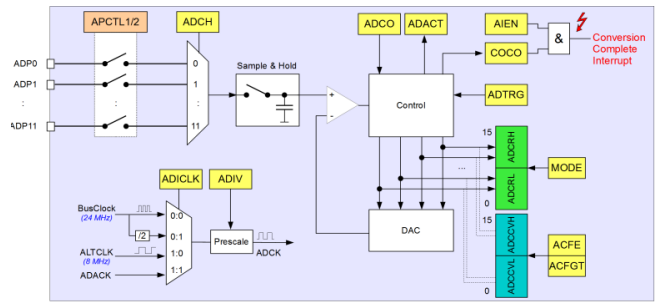

The integrated A/D-Converter does comparisons step by step, beginning with the MSB. Simply its a binary search through comparing. The more Bits the generated digital

word has, the closer the proximity will be.

During the conversion, the input voltage is kept steady (Sample & Hold).

12.3 Function Scheme & Control Register

ADCO: 1x, continuous

ADACT: busy

ADTRIG: ADCSC1 wr, ADHWT pin

MODE: 8, 10, 12bit

ACFE: enable

ACFGT: less, greater

0x0010	ADCSG1	COCO	AIEN	ADCO	ADCH					Status/Control 1
0x0011	ADCSG2	ADACT	ADTRG	ACFE	ACFGT	0	0	R	R	Status/Control 2
0x0012	ADCRH	0	0	0	0	ADR11	ADR10	ADR9	ADR8	Result High
0x0013	ADCLR	ADR7	ADR6	ADR5	ADR4	ADR3	ADR2	ADR1	ADRO	Result Low
0x0014	ADCCVH	0	0	0	0	ADCV11	ADCV10	ADCV9	ADCV8	Compare High
0x0015	ADCCVL	ADCV7	ADCV6	ADCV5	ADCV4	ADCV3	ADCV2	ADCV1	ADCV0	Compare Low
0x0016	ADCFG	ADLPC	ADIV	ADLSMP	MODE			ADICLK		Configuration
0x0017	APCTL1	ADPC7	ADPC6	ADPC5	-	ADPC3	ADPC2	ADPC1	ADPC0	Pin Control 1
0x0018	APCTL2	-	-	-	-	ADPC11	ADPC10	ADPC9	ADPC8	Pin Control 2

12.4 Code Sample

```
#define ADC_RES_8BIT 0
#define ADC_RES_10BIT 2
#define ADC_RES_12BIT 1

// init, using - high speed mode, ADCK = 6 MHz
// (busclock / 4), enable four line sensor
void adcInit(void)
{
    // max conversion time: 40x ADCK cycles + 5
    // bus clock cycles
    // 40x 167ns + 5x 42ns = 7.21us
    // long sample time for higher conversion
    // accuracy
    ADCCFG_ADLPC = 0; // high speed
    ADCCFG_ADLSMP = 1; // long sample time
    ADCCFG_ADICLK = 0; // bus clock = 24 MHz

    // create mask for only reading used channels
    // , prevents external noise
    APCTL1 = 0xF0; // LsL, LsML. LsMR,
    // LsR
    // APCTL1 = (1<<adcLsL) | (1<<adcLsML) | (1<<
    // adcLsMR) | (1<<adcLsR);

    // valid clock: 0.4 - 4 MHz if ADLPC = 1
    ADCCFG_ADIV = 2; // 0=/1, 1=/2,
    // 2=/4, 3=/8

    // setup interrupt (compare value - 12bit)
    ADCCV = 0x05;
    // define if trigger on less (0) or greater
    // (1) then received value
    ACFG_T = 0; //
    ACFE = 1; // enable compare function
    AIEN = 1; // enable interrupt
    // to reset the interrupt flag (COCO), either
    // write to ADCSC1 or read ADCRL
}

// 12 bit resolution (most of the time to much
// noise prever 10/8 Bit)
uint16 adcGet12BitValue(AdcChannels ch)
{
    // set resolution (could also be
    // ADC_RES_10BIT or ADC_RES_12BIT)
```

13.8 Contextswitch

13.9 Parallelism

Tasks that are dependent from each other must *cooperate*. We can differentiate between:

Synchronisation

Semaphore was Train Signal
Mutex Mutual exclusion
Flags Signaling Flags

Communication

Mailbox
Message Queues

- Tasks can simply communicate over **data structures**
- Example: Time - h and min values stored each as global 8-bit variables (1 task Wr / 1 task Rd)
- For coherent data **Mutual exclusion** is imminent
- Methods for Mutual Exclusion are; **Disable Scheduler and Interrupts, Semaphors**

13.9.1 Semaphore

```
// Define Semaphore
OS_EVENT *sem_X;
// Create Semaphore and set to 100
sem_X = OSSemCreate(100);
INT8U err;
// Wait for free Semaphore Timeout = 0 (endless)
// critical Code...
OSSemPend(sem_X, 0, &err);
// Free Semaphore
OSSemPost(sem_X);
```

13.9.2 Mutex

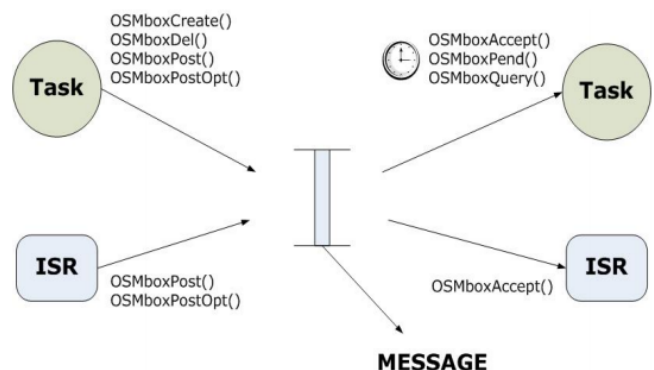

```
// Define Mutex
OS_EVENT *mut_X;
INT8U err;
// Create Mutex with Priority (prio is
// overtaken when mutex gets owned)
mut_X = OSMutexCreate(9, &err)
// Wait for freeing of Mutex, Timeout = 0 (
// endless)
OSMutexPend(mut_X, 0, &err);
// Free Mutex
OSMutexPost(mut_X);
```

13.9.3 Flags

```
// Define Flag group
OS_FLAG_GRP *fg_x;
INT8U err;
// Create Flag group and init.
fg_x = OSFlagCreate(0x00, &err);
OS_Flags value;
// wait until BIT0 and BIT1 get set in the Flag
// group or the timeout expires
Value = OSFlagPend(fg_x, 0x01+0x02,
OS_FLAG_WAIT_SET_ALL, 10, &err);
```

13.9.4 Mailbox

```
// Define Mailbox
OS_EVENT *mBox;
// Create empty Mailbox
mBox = OSMboxCreate((void *) 0);
// Store Message in Mailbox
```

```
OSMBoxPost(mBox, &message);
INT8U err;
// Wait for a Message
OSMBoxPend(mBox, 0, &err);
```

13.9.5 Queue

```
// Define Message-Queue
OS_EVENT *queue;
// Array for Queue-Data
void *data[10];
// Create Message-Queue
queue = OSQCreate(data, 10);
// Add Message in Queue
INT8U err = OSQPost(queue, &message);
// Wait for a Message
void *msg = OSQPend(queue, 0, &err);
```

13.10 Priority Inversion

A low priority task blocks a higher priority task while accessing a common resource. This can happen while semaphores are used. Mutex have a solution, they will execute the part when the mutex is borrowed in an different priority, usually higher then everything else.

13.11 Code

```
// stacksize for all the task, can be
// differntly sized
#define TASK_STK_SIZE 128

#define PRIO_INIT 0
// always max. priority for the init task.
#define PRIO_BLINK_1 2
#define PRIO_BLINK_2 3
// mutex can be used to have different prios
// for the time the mutex is used
#define PRIO_MUT_DISP 1

// Array of type OS_STK stackmemory. needs to
// be done for every task
OS_STK InitTaskStack[TASK_STK_SIZE];
OS_STK Blink1Stack[TASK_STK_SIZE];
OS_STK Blink2Stack[TASK_STK_SIZE];

OS_EVENT *Mut_Displ;
OS_EVENT *Sem_Displ;

void Blink1(void *pdata)
```

```
{
    uint8 color,i,res;

    color=SSD1307_PIXEL_BLACK;
    (void)pdata;
    for(;;)
    {
        for(i=0;i<96;i++)
        {
            //OSMutexPend(Mut_Displ, 0, &res);
            OSSemPend(Sem_Displ, 0, &res);
            GDispl_DrawVLine(i,2,5,color);
            SSD1307_UpdateFull();
            //(void)OSMutexPost(Mut_Displ);
            (void)OSSemPost(Sem_Displ);

            PTFD_PTFD1 = !PTFD_PTFD1; //
            Blinking_LED
            OSTimeDly(20);
        }
        if(color==SSD1307_PIXEL_BLACK)
        {
            color=SSD1307_PIXEL_WHITE;
        }
        else
        {
            color=SSD1307_PIXEL_BLACK;
        }
    }
}

void Blink2(void *pdata)
{
    // same as blink1 with differnt OSTimeDly
    (46);
}

void InitTask(void* pdata)
{
    (void)pdata; // surpress compiler warning
    OSTimerInit(); // configer and start timer
    // ...
    // space for more initialisation
    // ...

    (void)OSTaskCreate(Blink1, (void*)0, &
        Blink1Stack[TASK_STK_SIZE-1],
        PRIO_BLINK_1);
    (void)OSTaskCreate(Blink2, (void*)0, &
        Blink2Stack[TASK_STK_SIZE-1],
        PRIO_BLINK_2);

    (void)OSTaskDel(OS_PRIO_SELF); // close
    init task
}

void main(void)
{
    OSInit(); // OS initialisieren
    // Task Ptr, Argument Ptr, Stack Ptr, Task
    Id = Prio
    OSTaskCreate(InitTask, (void*)0, &
        InitTaskStack[TASK_STK_SIZE-1],
        PRIO_INIT);
    // Vor Aufruf von OSStart(..) muss
    mindestens 1 Task erzeugt sein
    OSStart(); // start OS
}
```
